

* Indirect Searches for NP in Flavour Physics.

Frederic Teubert CERN, PH Department

Indirect Searches for NP

If the **energy** of the particle collisions is high enough, we can discover NP detecting the production of "real" new particles.

If the **precision** of the measurements is high enough, we can discover NP due to the effect of "virtual" new particles in loops.

But not all loops are equal... In "non-broken" gauge theories like QED or QCD the "decoupling theorem" (Phys. Rev. D11 (1975) 2856) makes sure that the contributions of heavy (M>q²) new particles are not relevant. For instance, you don't need to know about the top quark or the Higgs mass to compute the value of α (M_Z²).

However, in broken gauge theories, like the weak and yukawa interactions, radiative corrections are usually proportional to Δm^2 .

Indirect Searches for NP

Therefore, NP contributions in loops are suppressed by the size of the isospin breaking value Δm^2 . Larger effects of NP expected in (t,b)/ τ .

Moreover, through the study of **the interference of different quantum paths** one can access not only to the magnitude of the couplings of NP, but also to their **phase** (for instance, by measuring CP asymmetries).

Within the SM, **only weak interactions through the Yukawa mechanism** can produce a **non-zero CP** asymmetry. It is indeed a big mystery why there is no CP violation observed in strong interactions (axions?).

Therefore, precision measurements of FCNC can reveal NP that may be well above the TeV scale, or can provide key information on the couplings and phases of these new particles if they are visible at the TeV scale.

Direct and indirect searches are both needed and equally important, complementing each other.

Status of Searches for NP

So far, no significant signs for NP from direct searches at the LHC while a (the SM?) Scalar Boson has been found with a mass of ~ 126 GeV/c².

Before LHC, expectations were that "*naturally*" the masses of the new particles would have to be light in order to reduce the "fine tuning" of the EW energy scale. Theory departments were (are?) full of advocates of supersymmetric particles appearing at the TeV energy scale.

However, the absence of NP effects observed in flavour physics, even before LHC, implies some level of "fine tuning" in the flavour sector \rightarrow NP FLAVOUR PROBLEM

"Non-natural" solution:

 \rightarrow Minimal Flavour Violation (MFV).

As we push the energy scale of NP higher, the NP FLAVOUR PROBLEM is reduced, <u>hypothesis</u> like MFV look less likely \rightarrow chances to see NP in flavour physics have, in fact, increased when Naturalness (in the SM Scalar sector) seems to be less plausible!

N.Arkani-Hamed, Intensity Frontier Workshop (Nov 2011,Washington)

(a Turalness' Loss = Flavor Gain 10 TeV KM-1:ke TeV TAWII

Flavour in the SM:Yukawa Mechanism in the quark sector.

$$-\mathcal{L}_{\text{Yukawa}}^{\text{SM}} = Y_d^{ij} \bar{Q}_L^i \phi D_R^j + Y_u^{ij} \bar{Q}_L^i \tilde{\phi} U_R^j + Y_e^{ij} \bar{L}_L^i \phi E_R^j + \text{h.c.}$$

 $\lambda_d = \operatorname{diag}(y_d, y_s, y_b) , \quad \lambda_u = \operatorname{diag}(y_u, y_c, y_t) , \qquad y_q = \frac{m_q}{n} .$

$$Y_d = \lambda_d , \qquad Y_u = V^{\dagger} \lambda_u ,$$

The quark flavour structure within the SM is described by 6 Yukawa couplings and 4 CKM parameters. In practice, is convenient to move the CKM matrix from the Yukawa sector to the weak current sector:

In the SM quarks are allowed to change flavour as a consequence of the Yukawa mechanism. Using Wolfenstein parameterization (A, λ , ρ , η):

Flavour Beyond the SM

Consider a two Higgs doublet model with different vacuum expected values, v_1 and v_2 .

In general, the diagonalization of the mass matrix will not give diagonal Yukawa couplings \rightarrow large FCNC.

$$\overline{d}_{R,i}(\hat{h}_{d,1}^{ij} \phi_1 + \hat{h}_{d,2}^{ij} \phi_2) d_{L,j}$$
$$\hat{m}_d^{ij} = \hat{h}_{d,1}^{ij} \mathbf{v}_1 + \hat{h}_{d,2}^{ij} \mathbf{v}_2$$

Ok, let's assume that each Higgs doublet couples only to one type of quarks, i.e. something like **SUSY**. But then, at some energy scale, this symmetry breaks \rightarrow expect again large FCNC, if the SUSY scale is not far away.

Minimal Flavour Violation: at tree level the quarks and squarks are diagonalized by the same matrices \rightarrow no FCNC at tree level, like in the SM.

At loop level, however, expect both Higgs doublets to couple to up and down sectors \rightarrow expect large FCNC at large tan β .

Two indirect paths to study Higgs BSM:

- I. Precise measurements of the Higgs boson properties.
- 2. Precise measurements of FCNC.

Tree vs loop measurements

(A, λ , ρ , η) are not predicted by the SM. They need to be measured!

If we assume NP enters only (mainly) at loop level, it is interesting to compare the determination of the parameters (ρ , η) from processes dominated by tree diagrams (V_{ub} , γ ,...) with the ones from loop diagrams ($\Delta M_d \& \Delta M_s$, β , ε_K ,...).

Need to improve the precision of the measurements at tree level to (dis-)prove the existence of NP contributions in loops.

Experimental Facilities

LHC is working like a dream!

Since the first proton-proton collisions at the LHC at 7 TeV in Spring 2010, the progress has been fantastic!

In 2012 LHC delivered routinely peak luminosities of 4x10³³/cm²/sec at 8 TeV, for a total of 23/fb to ATLAS&CMS (6/fb in 2011 at 7 TeV).

LHCb took data at a constant luminosity 0.4x10³³/cm²/sec thanks to luminosity leveling, for a total of 2.2/fb at 8 TeV delivered (1.2/fb in 2011 at 7 TeV).

LHCb average number of visible pp collisions per bunch crossing ~2, while for ATLAS/CMS is ~20.

LHC is working like a dream!

The bb x-section was measured by LHCb at 7/8 TeV to be: 3×10^{11} fb (PLB 694 (2010) 209 and JHEP 06 (2013) 064). The cc x-section ~20 times higher! (Nuclear Physics B 871 (2013) 1)

About 40% of the b-quarks produced at the LHC fragments into B^{\pm} and another 40% into B^{0} , while 10% fragments into B_{s} and 10% into baryons.

However at the LHC, the two b-quarks are produced incoherently \rightarrow extra dilution factor in the tagging of neutral mesons.

The LHCb detector acceptance ranges between ~10% for $B_s \rightarrow \mu^+ \mu^-$ decays to, for instance, ~5% for $B_s \rightarrow J/\Psi[\mu^+ \mu^-]\Phi[K^+K^-]$.

Rule of thumb:

<u>I/fb at 7TeV at LHCb is equivalent to (Ik-5k)/fb at the e⁺e⁻ B-factories</u> before tagging for B⁰/B[±] decays into charged particles.

...and the LHCb performance is up to it!

 $B_s \rightarrow D_s [K K^+\pi^-]\pi^+$

Hadron trigger ~34k candidates/fb

Proper time resolution ~ 44 fs (to be compared with $2\pi^{-1}\Delta m_s^{-1}$ ~350 fs)

Effective tagging ~3.5%

New J. Phys. (2013) 053021

 $\Delta m_s = 17.768 \pm 0.023 \pm 0.006 \text{ ps}^{-1}$

c.f. CDF with proper time resol. ~87 fs $\Delta m_s = 17.77 \pm 0.10 \pm 0.07 \text{ ps}^{-1}.$

Precision measurements at hadron colliders are not any more a dream!

V_{ub} phase: Experimental Strategies

q=u: with D and anti-D in same final state $B^{\pm} \rightarrow DX_s X_s = \{K^{\pm}, K^{\pm}\pi\pi, K^{*\pm}, ...\}$

q=s: Time dependent CP analysis. Inteference between B_s mixing and decay.

 $B_{s} \rightarrow D_{s}^{\pm} K^{\mp}$

In the case q=u the experimental analysis is relatively simple, selecting and counting events to measure the ratios between B and anti-B decays. NP contributions to D mixing are assumed to be negligible or taken from other measurements.

However the extraction of γ requires the knowledge of the ratio of amplitudes $(r_{B(D)})$ and the difference between the strong and weak phase in B and D decays ($\delta_{B(D)}$) \rightarrow charm factories input (CLEO/BESIII).

In the case q=s, a time dependent CP analysis is needed to exploit the interference between B_s mixing and decay. NP contributions to the mixing needs to be taken from other measurements ($B_s \rightarrow J/\Psi \phi$).

V_{ub} phase: B[±] Decays

Same argument works for $D\pi$ final states, but r_B (hence interference) is ~10 smaller.

A variation of the above methods, is when $D \rightarrow K_s h^+h^-$, (Giri, Grossman, Soffer and Zupan, PRD68, 054018 (2003)). A Dalitz analysis of the three-body decays allows for an increase in sensitivity.

and the second s

$\Delta F=2 Box$ Measurements

\triangle F=2 box in b \rightarrow d transitions: CP asymmetries in B, \rightarrow J/ Ψ K,

 $\tan \beta \approx \frac{\eta}{1-\rho} (1-\frac{\lambda^2}{2})$ To be compared with the indirect determination using "tree level measurements": $\beta = 24.9+0.8-1.9^{\circ}$

If we assume the SM, B-factories have measured the phase of V_{td} better than 4% from $b \rightarrow d$ transitions in box diagrams. However, NP must be contributing at some level! Therefore, the precise measurement of β is in fact, a precise measurement of $(\beta + \phi_{bd}^{NP})$. ϕ_{bd}^{NP} can be as large as O(5°) and still be consistent!

 \triangle F=2 box in b \rightarrow s transitions: CP asymmetries in B_s \rightarrow J/ $\Psi \Phi$

Sensitivity to the phase in the box diagram, through the interference between mixing and decay.

Angular analysis is needed in $\mathbf{B}_{s} \rightarrow \mathbf{J} / \Psi \Phi$ decays, to disentangle statistically the CP-even and CPodd components. Use the helicity frame to define the angles: $\theta_{\rm K}, \theta_{\mu}, \phi_{\rm h}$.

\triangle F=2 box in b \rightarrow s transitions

LHCb flavour tagging improved with the inclusion now of Kaon Same Side Tag: $\varepsilon D^2 = (3.13 \pm 0.23)\%$

\triangle F=2 box in b \rightarrow s transitions

The result of the LHCb angular analysis of $B_s \rightarrow J/\Psi \Phi$ decays with 1/fb (27.6k candidates, PRD 87 (2013) 112010) combined with the results using $B_s \rightarrow J/\Psi \pi\pi$ decays (PLB 713 (2012) 378) $\Phi_s = 0.01 \pm 0.07 \text{ (stat)} \pm 0.01 \text{ (syst) rad}$, i.e., gives: $\Phi_{s} = 0.6 \pm 4.0^{\circ}$

This result can be compared with the indirect determination using "tree measurements", $\Phi_{\rm s} = -2.3 + 0.1 \circ .1_{-0.3}$

Although, there has been **impressive progress** since the initial measurements at CDF/D0, the uncertainty needs to be further reduced for a meaningful comparison.

Meanwhile, other LHC experiments have started contributing. ATLAS tagged analysis with 5/fb (22.6k candidates) and ($\varepsilon D^2 = (1.45 \pm 0.05)\%$) of $B_s \rightarrow J/\Psi \Phi$ decays gives:

ATLAS-CONF-2013-039

 $\phi_s = 0.12 \pm 0.25$ (stat.) ± 0.11 (syst.) rad

which corresponds to $\Phi_s = 7 \pm 16^\circ$.

So far there is no evidence for NP contributions neither on $b \rightarrow d$ nor on $b \rightarrow s$ box diagrams.

\triangle F=2 box in b \rightarrow q transitions

$$\left\langle B_{q}^{0} \left| M_{12}^{SM+NP} \right| \overline{B}_{q}^{0} \right\rangle \equiv \Delta_{q}^{NP} \left\langle B_{q}^{0} \right| M_{12}^{SM} \left| \overline{B}_{q}^{0} \right\rangle$$

$$\Delta_{q}^{NP} = \operatorname{Re}(\Delta_{q}) + \operatorname{i} \operatorname{Im}(\Delta_{q}) = \left| \Delta_{q} \right| e^{i\phi^{\Delta q}}$$

No significant evidence of NP in B_d or B_s mixing . Remember that what is named SM prediction in these plots, is in fact the determination from other measurements (tree level).

New CP phases in box diagrams constrained @95%CL to be <12% (<20%) for B_d(B_s).

Need to increase precision to disentangle NP phases of few percent in B_d and B_s mixing

B_{d b}

 $B \rightarrow K^* \mu \mu$ is the golden mode to test new vector(-axial) couplings in $b \rightarrow$ s transitions.

 $K^* \rightarrow K\pi$ is self tagged, hence angular analysis ideal to test helicity structure.

Sensitivity to O_7 , O_9 and O_{10} and their primed counterparts. This analysis is bound to be **one of the stronger constraints** in models for NP with future statistics.

$$\frac{1}{\Gamma} \frac{\mathrm{d}^{3}(\Gamma + \bar{\Gamma})}{\mathrm{d}\cos\theta_{\ell}\,\mathrm{d}\cos\theta_{K}\,\mathrm{d}\phi} = \frac{9}{32\pi} \begin{bmatrix} \frac{3}{4}(1 - F_{L})\sin^{2}\theta_{K} + F_{L}\cos^{2}\theta_{K} + \frac{1}{4}(1 - F_{L})\sin^{2}\theta_{K}\cos2\theta_{\ell} \\ &- F_{L}\cos^{2}\theta_{K}\cos2\theta_{\ell} + \\ S_{3}\sin^{2}\theta_{K}\sin^{2}\theta_{\ell}\cos2\phi + S_{4}\sin2\theta_{\ell}\sin2\theta_{\ell}\cos\phi + \\ &S_{5}\sin2\theta_{K}\sin\theta_{\ell}\cos\phi + S_{6}^{s}\sin^{2}\theta_{K}\cos\theta_{\ell} + \\ S_{7}\sin2\theta_{K}\sin\theta_{\ell}\sin\phi + \\ &S_{8}\sin2\theta_{K}\sin2\theta_{\ell}\sin\phi + S_{9}\sin^{2}\theta_{K}\sin^{2}\theta_{\ell}\sin2\phi \end{bmatrix}$$

Results from **B-factories and CDF** very much limited by the statistical uncertainty. **LHCb** already has with 1/fb the largest sample (0.9k candidates). \triangle F=IEW penguins in b \rightarrow s transitions: B \rightarrow K* μ μ angular analysis

Hadronic uncertainties under reasonable control for:

00

Moreover, the dependence with form factors can be further reduced with a redefinition of observables:

$$\begin{aligned} A_{\rm T}^{(2)} &= \frac{2S_3}{(1-F_L)} \\ A_{\rm T}^{Re} &= \frac{S_6}{(1-F_L)} \\ P_4' &= \frac{S_4}{\sqrt{(1-F_L)F_L}} \\ P_5' &= \frac{S_5}{\sqrt{(1-F_L)F_L}} \\ P_6' &= \frac{S_7}{\sqrt{(1-F_L)F_L}} \\ P_8' &= \frac{S_8}{\sqrt{(1-F_L)F_L}} \end{aligned}$$

$$\begin{aligned} &\stackrel{1}{\tau} \frac{d^3(\Gamma + \bar{\Gamma})}{d\cos\theta_K \, d\phi} = \frac{9}{32\pi} \left[\frac{3}{4} (1-F_L) \sin^2\theta_K + F_L \cos^2\theta_K + \frac{1}{4} (1-F_L) \sin^2\theta_K \cos 2\theta_\ell \right] \\ &- F_L \cos^2\theta_K \cos 2\theta_\ell + \frac{1}{2} (1-F_L) A_{\rm T}^{(2)} \sin^2\theta_K \sin^2\theta_\ell \cos 2\phi + \frac{1}{\sqrt{F_L(1-F_L)}P_4' \sin 2\theta_K \sin 2\theta_\ell \cos \phi} + \sqrt{F_L(1-F_L)P_5' \sin 2\theta_K \sin \theta_\ell \cos \phi} + \frac{1}{\sqrt{F_L(1-F_L)}P_4' \sin 2\theta_K \sin 2\theta_\ell \cos \phi} + \sqrt{F_L(1-F_L)P_5' \sin 2\theta_K \sin \theta_\ell \sin \phi} + \frac{1}{\sqrt{F_L(1-F_L)}P_8' \sin 2\theta_K \sin 2\theta_\ell \sin \phi} + \frac{1}{\sqrt{F_L(1-F_L)}P_8' \sin 2\theta_K \sin 2\theta_\ell \sin \phi} + \frac{1}{\sqrt{F_L(1-F_L)}P_8' \sin 2\theta_K \sin 2\theta_\ell \sin \phi} \right] \end{aligned}$$

 $B \rightarrow K^* \mu \mu$ Angular Analysis Results

Folding technique ($\Phi \rightarrow \Phi + \pi$) for $\Phi < 0$, reduces the number of parameters to fit: F_1 , S_3 , S_6 and S_9 .

Within uncertainties observables are consistent with the SM.

q²(A_{FB}=0)=4.9±0.9 GeV²/c⁴

ATLAS, CMS B \rightarrow K* μ μ angular analysis

And fortunately also ATLAS and CMS with ~0.4k candidates in 5/fb start to contribute to this analysis. They are particularly competitive at large q^2 .

30

 $B \rightarrow K^* \mu \mu$ Angular Analysis Results

Other folding techniques, can give access to the rest of observables.

Most of measurements in good agreement with SM predictions. Only a hint of disagreement in P_5 at low q^2 . With more luminosity a full angular analysis (no folding) will allow to exploit the full statistical power of the data.

\triangle F=IEW penguins in b \rightarrow s transitions: Implications

FIG. 4: Improvement in the q^2 -dependence of P'_5 in the illustrative case $C_9^{NP} - C_{9'}^{NP} - -1.5$ (and NP contributions to the other Wilson coefficients set to zero).

$$O_{7} = \frac{m_{b}}{e} (\bar{s}\sigma_{\mu\nu}P_{R}b)F^{\mu\nu}, \qquad O_{8} = \frac{gm_{b}}{e^{2}} (\bar{s}\sigma_{\mu\nu}T^{a}P_{R}b)G^{\mu\nu\,a},$$

$$O_{9} = (\bar{s}\gamma_{\mu}P_{L}b)(\bar{\ell}\gamma^{\mu}\ell), \qquad O_{10} = (\bar{s}\gamma_{\mu}P_{L}b)(\bar{\ell}\gamma^{\mu}\gamma_{5}\ell),$$

$$O_{S} = m_{b}(\bar{s}P_{R}b)(\bar{\ell}\ell), \qquad O_{P} = m_{b}(\bar{s}P_{R}b)(\bar{\ell}\gamma_{5}\ell),$$

$$O_{S} = m_{b}(\bar{s}P_{R}b)(\bar{\ell}\ell), \qquad O_{P} = m_{b}(\bar{s}P_{R}b)(\bar{\ell}\gamma_{5}\ell),$$

SM predictions for P'₅ differ significantly between different authors.

Nevertheless, NP contributing to C₉ could provide a better fit to the data, and still be compatible with other measurements.

The increase in sensitivity of the analysis with 3/fb could already be tale-telling.

\triangle F=I Higgs penguins in b \rightarrow d,s transitions: B decays

The pure leptonic decays of **K**,**D** and **B** mesons are a particular interesting case of EW penguin. The helicity **suppression** of the vector(-axial) terms, makes these decays particularly sensitive to new (pseudo-)scalar interactions \rightarrow Higgs penguins!

These decays are well predicted theoretically, and experimentally are exceptionally clean. Within the SM,

Superb test for new (pseudo-)scalar contributions. Within the MSSM this BR is proportional to $\tan^6 \beta / M_{A^4}$

\triangle F=I Higgs penguins in b \rightarrow d,s transitions: B decays

Main difficulty of the analysis is large ratio B/S.

Assuming the SM BR then after the trigger and selection, CDF expects ~0.26 $B_s \rightarrow \mu \mu$ signal events/fb, ATLAS ~0.4, CMS ~0.8 while LHCb ~12 (6 with BDT>0.5).

The background is estimated from the mass sidebands. LHCb is also using the signal pdf shape from control channels, rather than just a counting experiment. All experiments normalize to a known B decay.

In the B_s mass window the background is completely dominated by combinations of real muons

(main handle is the invariant mass		ATLAS	CMS	CDF	LHCb
mass resolution is equivalent to a factor	Decay time resolution (B _s)	~100 fs	~70 fs	87 fs	45 fs
two increase in luminosity).	Invariant Mass resolution (2-body)	80 MeV/c ²	45 MeV/c ²	25 MeV/c ²	22 MeV/c ²

Therefore, for equal analyses strategies:

~1/fb at LHCb is equivalent to ~10/fb at CMS, ~20/fb at ATLAS/CDF.

\triangle F=1 Higgs penguins in b \rightarrow d,s transitions:ATLAS/CDF/D0 Results

\triangle F=I Higgs penguins in b \rightarrow d,s transitions: Results

\triangle F=I Higgs penguins in b \rightarrow s,d transitions: Implications

Latest results on $B_{(s)} \rightarrow \mu^+ \mu^-$ strongly constraint the parameter space for many NP models, complementing direct searches from ATLAS/CMS.

In particular, large $\tan \beta$ with light pseudo-scalar Higgs in CMSSM is strongly disfavored.

The precision achieved now is such that $B_{(s)} \rightarrow \mu^+ \mu^$ sensitivity to (Z, γ) penguin starts to compete with the golden mode $B \rightarrow K^* \mu^+ \mu^-$.

CLFV: Muon Decays

The discovery of neutrino oscillations implies CLFV at some level. Many extensions of the SM to explain neutrino masses, introduce large CLFV effects (depends on the nature of neutrinos, Dirac vs Majorana). Hence, CLFV is very relevant for "Flavour" and "Neutrino" physics!

There is one more very important advantage w.r.t. the quark sector: the reach for NP energy scale is not so much affected by QCD uncertainties in the SM predictions.

CLFV: Tau Decays

Tau Decays are less suppressed in the SM with Dirac massive $\,
u$.

The ratio between $\tau \rightarrow \mu \gamma$ and $\tau \rightarrow \mu \mu \mu$ is a very powerful test of NP models. The decay in 3 μ is interesting in models with no dipole dominance (e.g. scalar currents). Typically SUSY predictions in the range [10⁻¹¹-10⁻⁹].

Taus are harder to produce. While rates of $3 \times 10^7 \ \mu^+/\text{sec}$ have been achieved at PSI, the B-factories have produced the best limits on CLFV tau decays with production rates of $\sim 2 \times 10^9 \ \tau /\text{ab}^{-1}$ or $\sim 10^2 \ \tau /\text{sec}$.

However, at the LHC taus are copiously produced (mainly from charm decays, $D_s \rightarrow \tau \nu$). At 7 TeV pp collisions, $\sim 8 \times 10^{10} \tau$ /fb⁻¹ are produced or $\sim 10^5 \tau$ /sec. At 14 TeV pp collisions expect to double the rate (higher xsection) and double again (luminosity)!.

Best limits at 90% C.L., so far, from B-factories:
BR($\tau \rightarrow \mu \gamma$)Is it public

this limits
tausBABAR:4.4x10^{-8}3.3x10^{-8}42

Is it possible to exploit this large sample of taus at the LHC?

Tau Flavour Violation Decays at LHCb: $\tau \rightarrow \mu \ \mu \ \mu$

LHCb has performed for the first time at hadron colliders a search for $\tau \rightarrow \mu \mu \mu$ in I/fb at $\sqrt{s}=7$ TeV. The number of candidates is normalized to the number of $D_s \rightarrow \Phi[\mu \mu]\pi$, the measured bb and cc cross-section at LHCb, and the fractions of $B \rightarrow \tau$ and $D \rightarrow \tau$ from LEP/B-factories.

Search in bins of invariant mass, PID and topological discriminant. Distribution compatible with background hypothesis.

Main background in the sensitive bins $(D_s^+ \rightarrow \eta [\mu \ \mu \ \gamma] \mu \ \nu)$. LHCb results:

BR($\tau \rightarrow \mu \ \mu \ \mu$)<9.8(8.0)×10⁻⁸ at 95(90)% CL.

BELLE sensitivity x4 better with $\sim 0.8 \text{ ab}^{-1}$.

Again, expect large LFV effects at large $\tan \beta$

The **LHCb-upgrade** with 50 fb⁻¹ at $\sqrt{s} \sim 14$ TeV and **BELLE-II** with 50 ab⁻¹ should reach **BR(** $\tau \rightarrow \mu \ \mu \ \mu$)<[10⁻¹⁰-10⁻⁹] at 90% CL.

Conclusions

Interest in precision flavour measurements is stronger than ever. In some sense it would have been very "unnatural" to find NP at LHC7 from direct searches with the SM CKM structure.

There are few interesting anomalies, but in general the agreement with the SM is excellent \rightarrow large NP contributions, O(SM), ruled out in many cases.

There is a priory as many good reasons to find NP by measuring precisely the couplings of the new scalar boson, as by precision measurements in the flavour and neutrino sectors!

The search has just started at LHCb with (1+2)/fb at LHC(7+8)TeV.

LHCb upgrade plans to collect ~50/fb with a factor ~2 increase in bb and cc cross-section. ATLAS/CMS plan to collect ~300/fb and Belle-II plans to collect ~50/ab before HL-LHC era.

We don't know yet what is the scale of NP \rightarrow cast a wide net!

Don't give up yet!

b→u: Charged Higgs at tree level?

For some time the measured $BR(B \rightarrow \tau \nu)$ has been about a factor two higher than the CKM fitted value (3σ) , in better agreement with the inclusive V_{ub} result (about 30% higher than exclusive). Measurement very challenging at hadron colliders.

On the other hand, we knew from LEP: $W \rightarrow \tau \nu / W \rightarrow \nu \sim 1.06 \pm 0.03$

Summer 2012 **Belle** presented a more precise hadron tag analysis, in better agreement with the fitted CKM value:

World average BR(B $\rightarrow \tau \nu$))_{exp} = (1.15±0.23)x10⁻⁴ vs CKM fit:(0.83±0.09)x10⁻⁴

b→c: Charged Higgs at tree level?

BABAR also presented by Summer 2012 a more precise measurement of $BR(B \rightarrow D(^*) \tau \nu)/BR(B \rightarrow D(^*)|\nu)$. Ratio cancels V_{cb} and QCD uncertainties. Combined D and D* BABAR results are **3.4** σ higher than SM

 $B(B^+ \rightarrow \tau^+ v) (10^4)$

SM

 $B \rightarrow \tau v$ measurement new world average

Belle should be able to reduce the uncertainties on $B \rightarrow D(*) \tau \nu$ at similar level than BABAR.

Not obvious NP explanation.

2HDM does not seem to be able

to explain the measured ratios at

BABAR, and in any case would be in tension with the latest measurements

of BR(B $\rightarrow \tau \nu$).

 $\tan \beta / m_{H^+} (GeV^{-1})$

 W^-/H

\triangle F=I Higgs penguins in s \rightarrow d transitions: Kaon decays

The pure leptonic decays of **K**,**D** and **B** mesons are a particular interesting case of EW penguin.

The helicity suppression of the vector(-axial) terms, makes these decays particularly sensitive to new (pseudo-)scalar interactions \rightarrow Higgs penguins!

BR($K_L \rightarrow \mu \ \mu$)=(6.84±0.11)×10⁻⁹ (BNL E871, PRL84 (2000)) measured to be in agreement with SM, but completely dominated by absorptive (long distance) contributions. In the case of $K_s \rightarrow \mu \ \mu$ the absorptive part is calculated to be 5×10⁻¹² as it is proportional to Im($V_{td}V_{ts}$). NP enhancement up to 10⁻¹¹ is possible.

The best existing limits on $K_s \rightarrow II$ at 90% C.L. are:

BR(K_s→ $\mu \mu$)<3.2x10⁻⁷ (PLB44 (1973)) BR(K_s→ee) <9x10⁻⁹ (KLOE, PLB672 (2009))

In particular a measurement of BR(K_s $\rightarrow \mu \mu$) of O(10⁻¹⁰-10⁻¹¹) would be a clear indication of NP in the dispersive part, and would increase the interest of a precise measurement of K⁺ $\rightarrow \pi^+ \nu \nu$. 50

\triangle F=I Higgs penguins in s \rightarrow d transitions: Kaon decays

LHC produces 10^{13} K_s/fb in the LHCb acceptance. Trigger was not optimized for this search in 2011 (it is for the 2012 data taking period).

Excellent LHCb invariant mass resolution critical to reduce peaking bkg.

Mass distribution compatible with bkg hypothesis:

BR(K_s $\rightarrow \mu \mu$)<11(9)×10⁻⁹ at 95(90)% C.L. ×30 improvement!

Excellent prospects to reach the interesting region ~10⁻¹¹ with the LHCb upgrade.

\triangle F=I Higgs penguins in c \rightarrow u transitions: Charm decays

Charm decays are complementary to B and K decays, because in the loops the relevant quarks are down-type rather than up-type.

Short distance contribution to $D \rightarrow \mu \mu$ decays is $O(10^{-18})$ within the SM.

Long distance contributions could be indeed much larger, but they are limited to be **below 6x10**⁻¹¹ from the existing **limits on D** $\rightarrow \gamma \gamma$:

 $\mathcal{BR}^{(\gamma\gamma)}(D^0 o \mu^+\mu^-) \simeq 2.7 imes 10^{-5} \mathcal{BR}(D^0 o \gamma\gamma)$ Phys.Rev. D66 (2002) 014009

BABAR result BR(D $\rightarrow \gamma \gamma < 2.2 \times 10^{-6} @90\%$ C.L.) Phys. Rev. D85 (2012) 091107

Charm decays complement K and B mesons decays.

\triangle F=I Higgs penguins in c \rightarrow u transitions: Charm decays

Experimental control of the peaking background is crucial ($D \rightarrow \pi\pi$). Best existing limit before spring 2012 was from **Belle**, <1.4x10⁻⁷@90%C.L.

BABAR, arXiv:1206.5419, update for summer 2012 show a slight excess of candidates (8 observed, 3.9±0.6 bkg) which was interpreted as a two-sided 90% C.L. limit, [6,81]x10⁻⁸, in tension with LHCb results.

LHCb will study the theoretical clean region between 8x10-9 and 10-11

\triangle F=2 box in b \rightarrow s transitions

However, there is a two fold ambiguity in the differential decay rates:

$$(\phi_{\mathfrak{s}}, \Delta \Gamma_{\mathfrak{s}}, \delta_{0}, \delta_{\parallel}, \delta_{\perp}, \delta_{\mathrm{S}}) \longmapsto (\pi - \phi_{\mathfrak{s}}, -\Delta \Gamma_{\mathfrak{s}}, -\delta_{0}, -\delta_{\parallel}, \pi - \delta_{\perp}, -\delta_{\mathrm{S}})$$

This ambiguity is resolved by LHCb using the dependence of the phase difference between P-wave and Swave.

The physical solution is found to be the blue points (the other solution, red points, is not compatible), therefore:

\triangle F=2 box in b \rightarrow q transitions (D0 flavour specific asymmetries)

Could it be that we have large NP effects in the absorptive part?

 $\mathbf{a}^{q}_{fs} = | \Gamma^{q}_{12} / \mathbf{M}^{q}_{12} | sin(\phi_{q})$

$$B_{q}^{0} \rightarrow D_{q}^{-}\mu^{+}\nu_{\mu}: \text{Allowed} \xrightarrow{p_{q}^{0}} D_{s}^{-} D_{s}^{$$

 a_{sl}^{d}

D0 inclusive measurement of the dimuon asymmetry is interpreted as a linear combination of $a_{sL}(B_d)$ and $a_{sL}(B_s)$ which depends on the fraction of B_d and B_s in the data sample. No production asymmetry at pp colliders. Detector asymmetry controlled by switching magnet polarity.

D0 Dimuon:
$$A_{sL}^{b} = (-0.787\pm 0.172(stat)\pm 0.093(syst))\%$$
 (3.9 σ)
PRD 84 (2011) 052007 Systematic uncertainty drastically reduced by
assuming the bkg from the single-muon asymmetry.
and splitting the data sample in low(high) IP:
 $a_{sL}(B_d) = (-0.12\pm 0.52)\%$, $a_{sL}(B_s) = (-1.81\pm 1.06)\%$
Moreover, D0 has also measured: PRD 86 (2012) 072009,
PRL 110 (2013) 011801
Using $B_d \rightarrow \mu^+ D_s^{(*)-}$: $a_{sL}(B_d) = (0.68\pm 0.45(stat)\pm 0.14(syst))\%$
Using $B_s \rightarrow \mu^+ D_s^{(*)-}$: $a_{sL}(B_s) = (-1.12\pm 0.74(stat)\pm 0.17(syst))\%$
 55

\triangle F=2 box in b \rightarrow q transitions (LHCb flavour specific asymmetries)

LHCb needs to add more channels and more data and a precise measurement of $A_{SL}(B_d)$ to be able to conclude. However there is already a clear tension between D0 $a_{SL}(B_s)$ and the measurements of ($\Delta \Gamma_s, \Phi_s$.)

 \triangle F=2 box in b \rightarrow q transitions: (NP in absorptive part)

LHCb needs to add more channels and more data and a precise measurement of $A_{SL}(B_d)$ to be able to conclude.

\triangle F=2 box implications

△F=I QCD (Strong) Penguins

 \triangle F=I in c \rightarrow u QCD penguins: "Direct" CP violation in Charm decays

No evidence yet of CP violation in the interference between mixing and decay in the Charm system. Could we have large (unexpected) "direct" CP violation in Charm (penguin) decays?

A priori, consensus was CP violation O(1%) would be "clear" sign for NP.

Within the SM, use of U-spin and QCD factorization leads to $\Delta A_{CP} \sim 4$ Penguin/Tree $\sim 0.04\%$.

 $\Delta A_{CP} = A_{CP}(K^+K^-) - A_{CP}(\pi^+\pi^-)$ cancels detector and production asymmetries to first order. The SM and most NP models predicts opposite sign for KK and $\pi\pi$, hence no sensitivity lost by taking the subtraction.

 $D^{*\pm} \rightarrow D^0$ [h⁺h⁻] π^{\pm} charge of the pion determines the flavour of D^0 . Most of the systematics cancel in the subtraction, and are controlled by swapping the LHCb magnetic field.

There is no problem to enhance ΔA_{CP} in NP models, the question is really if subleading SM contributions are well under control. For instance, the U-spin approximation is challenged by the measurement $B(D \rightarrow m) \sim 2.8 B(D \rightarrow KK)$.

 \triangle F=I in c \rightarrow u QCD penguins: Direct CP violation in Charm decays

LHCb first evidence for direct CP violation in charm decays with 0.6/fb:

△A_{CP}=(-0.82±0.24)% LHCb (0.6/fb) (PRL 108, 111602 (2012))

confirmed later by: $\Delta A_{CP} = (-0.62 \pm 0.23)\% \text{ CDF}$ (PRL 109, 111801 (2012)) $\Delta A_{CP} = (-0.87 \pm 0.41)\% \text{ BELLE}$ (Preliminary ICHEP 2012)

However, a more precise LHCb update with 1/fb does not confirm the previous tendency:

ΔA_{CP}=(-0.34±0.18)% LHCb (1/fb) (LHCb-CONF-2013-003)

Moreover, an independent analysis using $B^{\pm} \rightarrow D^0$ [h⁺h⁻] $\mu^{\pm} \nu X$, where the charge of the muon determines the flavour of D⁰, does not confirm either the initial hints:

ΔA_{CP}=(0.49±0.33)% LHCb (semil, I/fb) (PLB 723, (2013) 33)

p-value average = 2.4%(or equivalent to 2.3σ)

p-value (no CP-violation) = 0.15%(or equivalent to 3.2σ)

LHCb results dominated by statistics. Situation should become more clear with the analysis of the available 3/fb.

But it is clear that we are moving towards smaller effects, hence difficult to differentiate NP from SM.

No significant discrepancy between $b \rightarrow ccs$ and s-penguin measurements. However, there may be a tendency and effects $O(\delta\beta \sim 4^{\circ})$ are not excluded.

The effect of the same s-penguins can be measured at LHCb both in the B_d and B_s system. Belle-II may improve further on B_d decays.

An O(few degrees) measurement can reveal NP effects in s-penguins

(Parenthesis)Advantages/Disadvantages of Existing Facilities

Common "past" knowledge:

lepton colliders \rightarrow precision measurements vs hadron colliders \rightarrow discovery machines

After the achievements at the Tevatron in precision EW measurements (W mass) and B-physics results (Δm_s) and in particular the astonishing initial performance of the LHC detectors (LHCb in particular), I think the above mantra **is over simplistic and not true**.

Lepton colliders have the advantage of a known CoM energy, better selection efficiencies and high peak luminosities (10^{34} - 10^{36}) cm⁻²s. However, at the Y(4S) only _{B(d,u)} mesons are produced.

Hadron colliders have a very large cross-section (σ_{bb} (LHC7)~3×10⁵ σ_{bb} (Y(4S))), very performing detectors and trigger system. Effective tagging efficiency is typically ×10 better at lepton colliders.

Yields at LHCb and B-factories
